The functions:

```
function [realCepstrum, fs] = getRealCepstrum(speechSegment)

[windowedSignal, fs] = getWindowedSignal(speechSegment);
logMagnitudeSpectrum = getLogMagnitudeSpectrum(windowedSignal);
realCepstrum = ifft(logMagnitudeSpectrum);

end

%% get a 30 ms window of speech signal

function [windowedSignal, fs] = getWindowedSignal(inputFile)

windowDuration = 0.030; % in ms

[y, fs] = wavread(inputFile);
length = size(y, 1);
centralIndex = round(length/2);
M = round(windowDuration * fs);
```

```
startIndex = round(centralIndex - M/2);
windowedSignal = y(startIndex:startIndex + M-1);

end

%% get logarithm of the magnitude spectrum

function logMagnitudeSpectrum =
getLogMagnitudeSpectrum(windowedSignal)

mag = fft(windowedSignal);
logMagnitudeSpectrum = log(abs(mag));

end
```

The functions:

```
function [vocalTractResponse, w] =
getVocalTractResponse(speechSegment)

[speechCepstrum, fs] = getRealCepstrum(speechSegment);
lowTimeCepstrum = getLowTimeCepstrum(speechCepstrum, fs);
vocalTractResponse = abs(fft(lowTimeCepstrum));
vocalTractResponse = vocalTractResponse(1:
(length(vocalTractResponse)/2));

M = length(vocalTractResponse);
frequencies = (fs/M) * (0:M-1);
w = frequencies(:)/2;

end

%% do low-time liftering for vocal tract estimation
```

```
function lowTimeCepstrum = getLowTimeCepstrum(speechCepstrum,
fs)

cutoffLength = fs * .003; % take 20 or 15
speechCepstrum = speechCepstrum(1:round(length(speechCepstrum)/
2));
lowTimeCepstrum = speechCepstrum;
lowTimeCepstrum((cutoffLength+1):end) = 0;

end
```

The LPC function (adapted from previous assignment):

```
function [LPCSpectrum, narrowbandSpectrum, w] =
getLPCSpectrum(speechSegment, poleOrder)

if nargin < 2, poleOrder = 10; end

[windowedSignal, fs] = getWindowedSignal(speechSegment);
M = length(windowedSignal);
% the narrowband spectrum first
narrowbandSpectrum = log(abs(fft(windowedSignal)));
narrowbandSpectrum = narrowbandSpectrum(1:round(M/2));

preEmpdSignal = preEmphasize(windowedSignal);
LPCoeffs = getLPCoefficients(preEmpdSignal, poleOrder);
frequencies = (fs/M) * (0:M-1);

denominator = 0;
numerator = 1;

for k = 1:poleOrder
    denominator = denominator + (LPCoeffs(k) * (exp(-1i * 2 * pi
* frequencies ./ fs) .^ (k-1)));
end

H = numerator ./ denominator;
LPCSpectrum = log(abs(H));
LPCSpectrum = LPCSpectrum(1:round(M/2));
w = frequencies(1:round(M/2));
LPCSpectrum = LPCSpectrum(:);
narrowbandSpectrum=narrowbandSpectrum(:);
w=w(:);

end
```

```
%% get a 30 ms window of speech signal

function [windowedSignal, fs] = getWindowedSignal(speechSegment)

windowDuration = 0.030; % in ms
[y, fs] = wavread(speechSegment);

```

The vocal tract response is the DFT of the first 3-4ms window of the cepstrum of the signal. We did a low-time liftering of the cepstrum using a 3 ms window and then took the DFT which is supposed to be equal to the log of abs(V(z)). Here z = e^(jω). The excitation component is supposed to be in the high quefrencies of the cepstrum.

s(n) = e(n) * v(n) and S(z) = E(z)V(z)

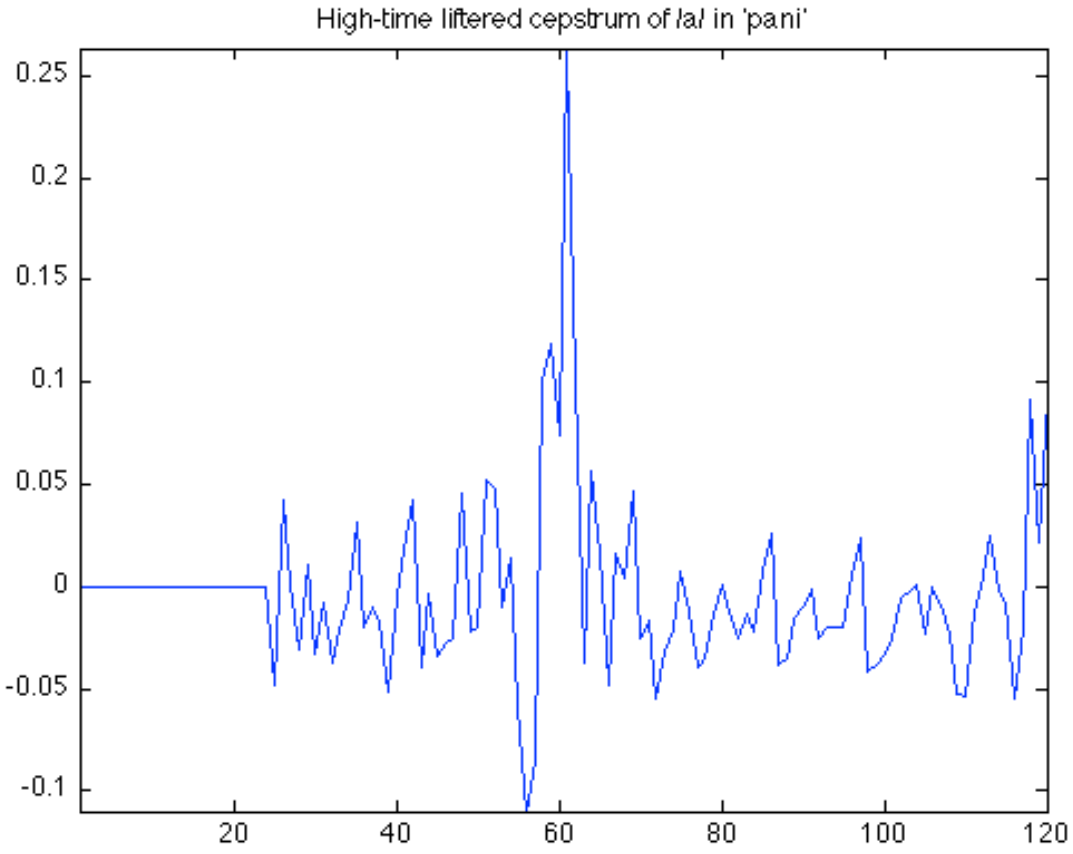
log(|S(z)|) = log(|E(z)|) + log(|V(z)|)
e'(n) and v'(n) are the IDFT of log(|E(z)|) and log(|V(z)|) respectively. v'(n) corresponds to the first 3-4ms window of the cepstrum. e'(n) is impulsive and periodic for voiced sounds.

Question 3

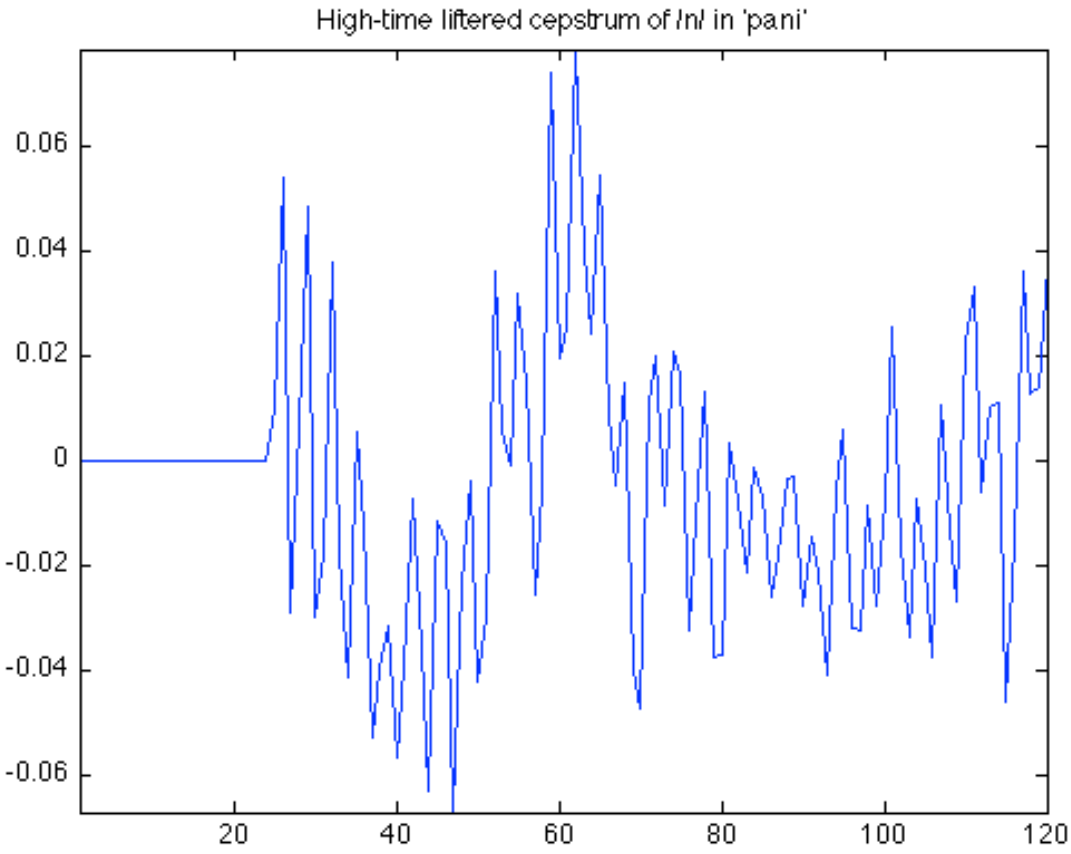
The pitch estimation is done by finding the maximum of the peaks in the high-time liftered part of the cepstrum. The pitch period is the time corresponding to the maximum peak from time '0'. If there are more than one maximum peaks then we consider the first one.

Pitch Estimation

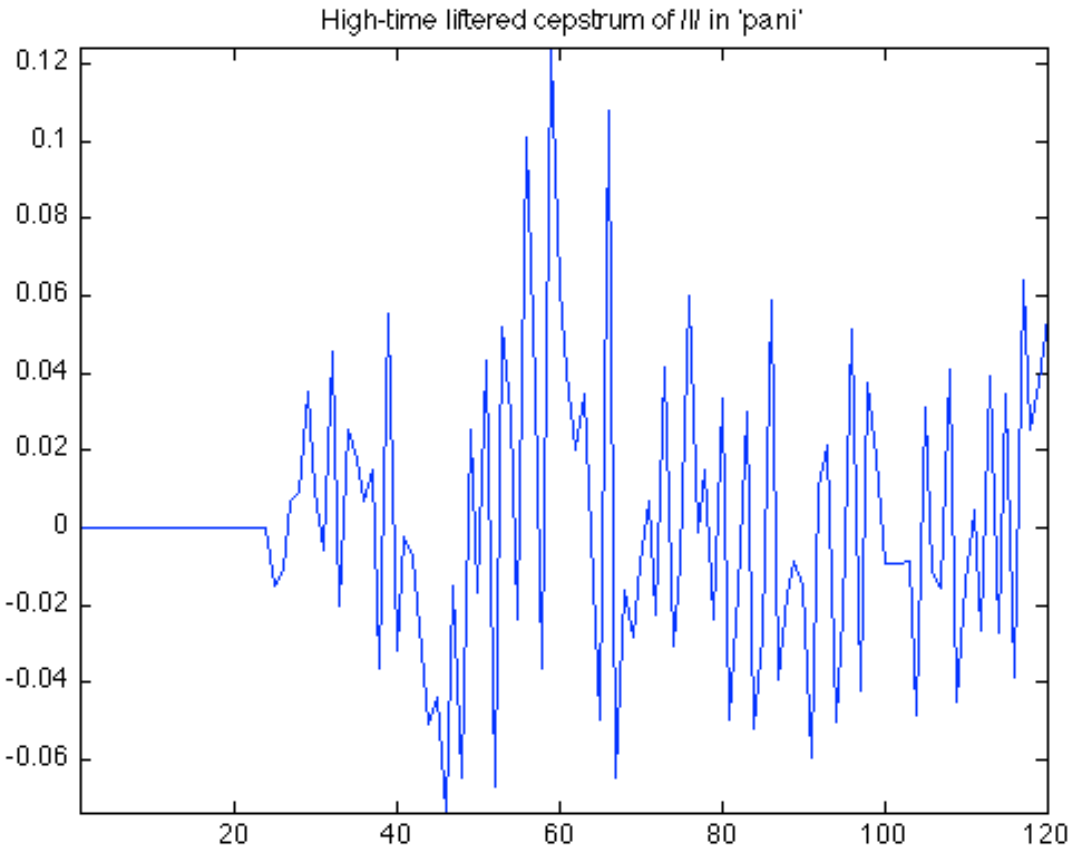
Pitch for /a/ in 'pani': 133.3333Hz



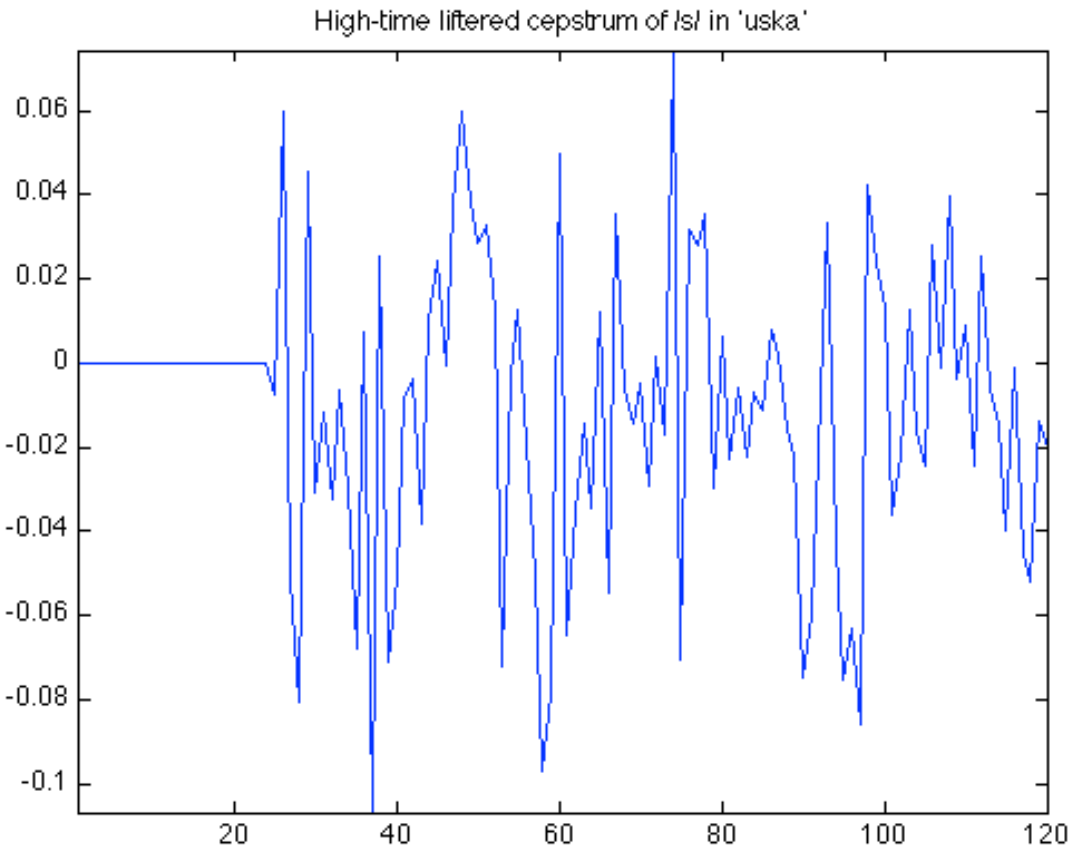
Pitch for /n/ in ‘pani’: 131.1475Hz



Pitch for /l/ in ‘pani’: 137.9310Hz



Pitch for /s/ in ‘uska’: 109.5890Hz



High-time liftered cepstrum of /s/ in 'uska'
